

If you choose to get the AstraZeneca vaccine, your risk of death from TTS is **1 in a million**,

and your risk of getting TTS at all is less than 30 in a million.

Thrombosis with thrombocytopenia syndrome (TTS) is a rare condition reported in some people who have received adenoviral vector COVID-19 vaccines. TTS is different to other more common blood clotting conditions as it is triggered by an immune response.

Having a history of blood clots, like deep vein thrombosis (DVT), **does not** increase your risk of TTS due to the AstraZeneca vaccine.

But how small is 1 in a million?

1 minute in **2 years**

8 cm along the way from **Brisbane to the Gold Coast** (80 km)

1 single hair out of a total of **10 people's heads**

1 person out of **10 sold-out MCG stadiums**

and this orange dot out of **this entire graphic** →

1 in a million is really rare.

When considering vaccination against COVID-19, it's important to remember the **proven benefits vastly outweigh the really rare risks.**
